ES-62 is a phosphorylcholine (PC)-containing glycoprotein secreted by the filarial nematode Acanthocheilonema viteae that acts to modulate the host immune response to promote the establishment of chronic helminth infection. Reflecting its anti-inflammatory actions, we have previously reported that ES-62 protects mice from developing Collagen-Induced Arthritis (CIA); thus, as this helminth-derived product may exhibit therapeutic potential in Rheumatoid Arthritis (RA), it is important to understand the protective immunoregulatory mechanisms triggered by ES-62 in this model in vivo. We have established to date that ES-62 acts by down-regulating pathogenic Th17/IL-17-mediated responses and up-regulating IL-10. In addition, our studies have identified that IL-22, another member of the IL-10 family of cytokines, exerts dual pathogenic and protective roles in this model of RA with ES-62 harnessing the cytokine’s inflammation-resolving and tissue repair properties in the joint during the established phase of disease. Here, we discuss the counter-regulatory roles of IL-22 in the murine model of CIA and present additional novel data showing that ES-62 selectively induces γδ T cells with the capacity to produce IL-22 and that γδ T cells with the capacity to produce IL-22, but not IL-17, induced during CIA can be identified by their expression of TLR4. Moreover, we also show that treatment of mice undergoing CIA with the active PC moiety of ES-62, in the form of PC conjugated to BSA, is not only sufficient to mimic the ES-62-dependent suppression of pathogenic IL-17 responses shown previously but also that of the IL-22 and IL-10 up-regulation observed with the parasitic worm product during CIA. These findings not only reinforce the potential of IL-22, firstly described as a Th17-related pro-inflammatory cytokine, as a protective factor in arthritis but also suggest that drugs based on the PC moiety found in ES-62 may be able to harness the joint-protecting activities of IL-22 therapeutically.

Introduction
ES-62 is a phosphorylcholine (PC)-containing glycoprotein secreted by the rodent filarial nematode Acanthocheilonema viteae and a homologue of excretory-
secretory products that can be detected in the bloodstream of humans infected with *Brugia malayi* and *Onchocerca volvulus* [1]. Our early *in vitro* studies revealed that this parasite-derived molecule exhibits a broad range of immunomodulatory effects, for example the dampening of the pro-inflammatory responses of macrophages and dendritic cells [2, 3], that likely promote persistence of the parasite in the host without severely immunocompromising it. Although its mechanism of action is not yet fully understood, TLR4 is a major target of ES-62 [4] and most of its anti-inflammatory properties depend on its unusual post-translational addition of PC; thus, when PC is chemically linked to an irrelevant protein such as BSA or ovalbumin, as with ES-62, it inhibits full activation of macrophages and DCs following TLR stimulation in a TLR4-dependent manner [5].

In accordance with the Hygiene Hypothesis [6] that has led to the proposal that the recent dramatic increase in allergy and autoimmune diseases in industrialized countries is related to the eradication of parasitic infections, a wide range of studies have shown infection with helminths to be protective against such disorders in experimental models, suggesting that such parasites or their immunomodulatory products could be exploited therapeutically. Reflecting this, we have shown that treatment with ES-62, either prophylactically or therapeutically, reduces disease severity and incidence of Collagen-Induced Arthritis (CIA), a murine model of human Rheumatoid Arthritis (RA) [7] and PC-BSA is able to protect mice in a similar manner.
An increasing number of studies have shown that helminths and their secreted products exert their anti-inflammatory effects by actively modulating host immune effector mechanisms, for example, by reducing aberrant Th1 or Th2 responses and promoting IL-10-dependent regulatory pathways [10-12]. Indeed, some of these actions have been associated with the mechanism of action underlying ES-62-mediated protection in CIA. Thus, protection was first associated with suppressed Th1 responses, reduced levels of collagen-specific IgG2a antibodies and increased IL-10 production [7, 13]. However, ES-62 failed to protect against other Th1-driven models of disease [14, 15], suggesting that alternative pathways might be targeted in CIA. Indeed, ES-62-mediated protection was subsequently shown to be associated with down regulation of IL-17 production, a finding consistent with increasing evidence that this cytokine is a major pathogenic driver in RA as IL-17 induces hyperplasia and proliferation of synoviocytes, production of pro-inflammatory mediators and promotion of TLR-dependent responses and recruitment of immune system cells including T cells, B cells and neutrophils [16-18]. Interestingly, ES-62 down-regulates IL-17 production by a multi-pronged mechanism, inhibiting Th17 polarization both directly and indirectly, the latter via the suppression of IL-6 and IL-23 release by DCs, key cytokines in DC-priming of Th17 differentiation. ES-62 also targets DCs to modulate the cross-talk between γδ T cells and DCs, resulting in reduced levels of IL-17 production by the innate lymphocytes. Collectively, these actions result in down-regulated expression of IL-17 in the joints of mice with CIA and reduced synovial inflammation [19]. Importantly, as biologics targeting IL-17 have resulted in some opportunistic fungal infections under clinical trial, IL-17-producing NK cells which have been shown to be protective in such infections remain unaffected in ES-62-treated mice undergoing CIA [20]. Thus ES-62 attenuates IL-17-mediated responses without fully inhibiting them, as a result suppressing pathogenic, but not infection-combating sources of IL-17 and these findings may go some way to explaining why helminth infections or ES-62-based treatments do not substantially immunocompromise the host.

More recently, we have investigated the effect of ES-62 on another component of the IL-23/IL-17 inflammatory axis in autoimmune arthritis, namely IL-22 which had also been reported to be a pro-inflammatory cytokine in RA [21, 22]. Consistent with this, we showed that neutralisation of IL-22 prior to onset of disease blocks joint pathology. However, we have also shown that IL-22 is required for ES-62’s anti-arthritic effects, via a mechanism in which IL-22-signalling desensitizes synovial fibroblast (SF) responses to pro-inflammatory factors such as IL-17 in the joint [23]. As a result, SFs produce less IL-6 and the number of
neutrophils infiltrating the joints is significantly reduced. These findings are consistent with increasing evidence suggesting that IL-22 can play dual pathogenic and, reflecting its wound healing properties [24], protective roles in RA. It is therefore essential to fully understand the role(s) of IL-22 in the pathogenesis of arthritis and the resolution of inflammation and protection against joint damage induced by the helminth product in order to translate these potentially therapeutic actions to the clinic. The aim of this report is therefore to provide further insight into the sources of IL-22 modulated by ES-62 in mice with CIA and in particular we show that a subset of γδ T cells that express TLR4 in vivo is a major potential producer of such protective IL-22. In addition, we also report that PC-BSA mimics the ability of ES-62 to up-regulate IL-22 production during protection from CIA: thus as we have recently provided proof of principle that small drug-like PC-based compounds can be protective in mouse models of arthritis and asthma[9, 25], this latter finding highlights the novel potential of parasite-derived products to harness the therapeutic properties of IL-22 in RA.

**Material and Methods**

CIA. Animals were maintained in the Biological Services Units in accordance with the Home Office UK Licences PPL60/3580, PPL60/3119 and PIL60/12183 and the Ethics Review Boards of the Universities of Glasgow...

and Strathclyde. CIA was induced in male DBA/1 mice (8-10 weeks old; Harlan Olac; Bicester, UK) by intradermal immunization with bovine type II collagen (CII, MD Biosciences) in complete Freund’s adjuvant (FCA) and mice were treated with purified endotoxin-free ES-62 from A. viteae or PC-BSA (2 µg/dose) or PBS subcutaneously on days -2, 0 and 21[7, 8]. Mice were monitored for clinical symptoms of arthritis: severity scores represent 0=normal; 1=erythema; 2=erythema plus swelling; 3=extension of swelling; 4=loss of function, and the disease score is the sum for the four limbs.

**Ex vivo analysis.** DLN cells (10^6/ml) were stimulated in the presence and absence of PMA (50 ng/ml) plus ionomycin (500 ng/ml) for 1 h before being incubated with 10 µg/ml Brefeldin A (Sigma-Aldrich, UK) for 5 h at 37°C with 5% CO₂. Live cells were discriminated by the
LIVE/DEAD fixable aqua dye (BioLegend, UK) and phenotypic markers labelled using FITC-conjugated anti-CD49b (BioLegend, UK), APC-conjugated anti-γδ TCR (eBioscience, UK) and biotin-conjugated anti–TLR4 antibodies before the cells were fixed and permeabilized according to BioLegend protocols. Pacific Blue-conjugated streptavidin was used for detection of biotinylated antibodies. Cytokines were stained using PerCP-Cy5.5–conjugated anti–IL-17A (BioLegend, UK) or PE-conjugated anti–IL-22 antibodies (R&D Systems, UK) for 30 minutes prior to analysis by flow cytometry, gating according to appropriate isotype controls.

**Cytokine analysis.** Serum levels of IL-22 and IL-10 were determined by ELISA, according to the manufacturers’ recommendations (R&D Systems; Biolegend).

**Statistical analysis.** Data were analyzed by Student’s unpaired t-test. Articular scores were analysed by the Mann-Whitney test. P values *<0.05 were considered significant.

**Results and Discussion**

**ES-62 differentially regulates IL-22 production by γδ and NK T cells in DLN from mice undergoing CIA.** Protection by ES-62 in the CIA model has been associated with counter-regulation of IL-17 and IL-22 levels in serum and joints during the established phase of pathology, with exposure to the parasite product elevating IL-22 but reducing IL-17 levels. Similarly, exposure to ES-62 reduces IL-17, but not IL-22 production by DLN and joint cells *ex vivo* and analysis revealed these cytokines to be predominantly produced by distinct populations of cells at both sites. Moreover, whilst ES-62 inhibited the levels of both spontaneous and PMA/ionomycin-stimulated IL-17 production by CD4⁺ DLN cells, it only reduced the proportion of unstimulated CD4⁺ DLN cells expressing IL-22. However, although we have shown the parasite product to additionally suppress the levels of IL-17⁺ γδ T cells whilst leaving the levels of IL-17-producing NK cells unaffected, the effects of ES-62 on IL-22 production by these subsets of innate lymphocytes was not investigated. We therefore decided to evaluate this in order to potentially identify a source of protective IL-22 production in the DLN during CIA progression (Fig.1). Consistent with our previous observations that exposure to ES-62 appeared to have little effect on the levels of IL-22-producing DLN cells, whilst kinetic analysis suggested that the proportion of both NK and γδ T cells expressing IL-22 was elevated in those DLN from ES-62 exposed mice undergoing CIA following challenge (day 21; Fig. 1A&B), this only reached significance for γδ T cells (at d28; Fig. 1B). By contrast, the proportion of γδ IL-17⁺ but not NK IL-17⁺ T cells was reduced at this time point (Fig. 1C&D).

These data suggest that γδ T cells, which by bridging innate and adaptive immunity play important immunoregulatory roles in RA, are selectively targeted by ES-62 to modulate the IL-17/IL-22 balance in the CIA model to mediate its protective effects. Interestingly, this kinetic analysis also revealed, consistent with IL-22 playing a pathogenic role during the initiation phase of disease that the levels of IL-22-producing γδ T cells in the DLN peaked within about 7 days and then generally declined with disease progression in PBS-treated mice undergoing CIA. By contrast, and supporting their proposed protective role, exposure to ES-62 helps maintain the levels of IL-22⁺ γδ T cells at time points where pathology is normally established in the joint. Although we do not know whether these cells can migrate to the joint and hence are representative of the IL-22-expressing lymphocyte-like cells previously shown to be elevated in ES-62-treated mice at this stage, these results could suggest that the observed increase of IL-22 in serum and joints of ES-62-treated mice might be a result of γδ T cell modulation rather than effects on conventional Th22 cells and may correlate with a report that CD4⁺ T cells isolated from synovial samples from RA patients were not able to produce IL-22.

**IL-22-producing γδ T cells, but not IL-17-producing γδ T cells, express Toll-like receptor 4 (TLR4).** It is not clear how ES-62 selectively targets γδ but not NK T cells, to render them respectively sensitive or resistant to modulation of IL-17/IL-22 production as both these cell types express pattern recognition receptors (PRR) important in CIA pathogenesis, such as TLR2 and ES-62 has been shown to subvert TLR signalling by down regulation of MyD88 in a variety of cell types. However, TLR4 is required for ES-62 action and although this PRR is not generally considered to be expressed by either γδ or NK T cells, TLR4⁺ γδ T cells have been described following burn injury and we have recently reported that a population of these cells, but not NK T cells can be found in the DLN of mice undergoing CIA. Thus, as TLR4 signalling has been reported to promote IL-17 production in γδ T cells isolated from lungs and lymphoid organs, we hypothesised that differential expression of this PRR may be involved in the selective regulation of IL-17/IL-22 production by γδ T cells and NK T cells in the CIA model. Although analysis of DLN cells from mice with CIA confirmed that TLR4⁺ γδ T cells did not express IL-17, perhaps surprisingly, but consistent with our previous findings that IL-17 and IL-22 were predominantly expressed by distinct populations of DLN cells, we observed a positive correlation between IL-22 expression and TLR4 on γδ, but not NK, T cells. This is the first observation of IL-22⁺ TLR4⁺ γδ T cells in the CIA model, and this subset may be analogous to the population of IL-22⁺ IL-17⁺ γδ T cells that has been shown to be protective in models of colon inflammation and lung...
for our development of small molecular analogues (SMAs) that mimic the anti-inflammatory ability of ES-62 in targeting pathogenic IL-17 responses in mouse models of arthritis and asthma[9, 25] and provide proof of concept for helminth-based drugs in inflammatory disease.

Although protection by PC-BSA against CIA also reflects down-regulation of pathogenic IL-17-dependent responses[9], our earlier studies suggested that PC does not necessarily reproduce all of the potentially protective effects of ES-62. For example, whilst PC conjugated to ovalbumin (PC-OVA) also ameliorated joint pathology in CIA models, it did not reduce the levels of potentially pathogenic anti-collagen IgG2a antibodies that are additionally decreased in ES-62-treated mice[8]. Therefore, we decided to investigate whether PC-BSA-mediated protection against CIA also reflected the up-regulation of IL-22 required for protection by ES-62 [23]. Interestingly therefore, whilst as we have shown previously, CIA mice presented elevated levels of IL-22 in serum compared to naive mice [23], it was found that such PC-BSA-treated mice exhibit significantly higher levels of IL-22 (3.5-fold increase, Fig.3C) and these serum levels of IL-22 inversely correlate with the clinical scores of the mice with CIA (Fig. 3E). Taken together, these findings corroborate our previous results observed with ES-62 and further support our hypothesis that the high levels of IL-22 observed in the serum of such mice during established disease, reflect the ability of this cytokine to resolve inflammation and joint damage properties of this cytokine in the CIA model[23].

Increased levels of IL-22 are also associated with elevated levels of IL-10 in serum obtained from PC-BSA-treated CIA mice. We have previously shown that protection against CIA in mice afforded by ES-62 is associated not only with inflammation-resolving IL-22 responses, but also with elevated splenic IL-10 production [7] which may reflect restoration of the levels of B cells with potential (IL-10-dependent) regulatory capacity [13]. Interestingly, therefore, a recent study has suggested that IL-22-mediated amelioration of CIA severity is associated with increased levels of IL-10[46]. Moreover, IL-22 has also recently been reported to suppress experimental autoimmune uveitis via generation of IL-10-producing regulatory CD11b+antigen presenting cells [47]. Therefore, we decided to evaluate the levels of IL-10 in serum of PC-BSA-treated mice, to determine whether there was concomitant up-regulation of IL-22 and IL-10 levels, as observed with ES-62. Indeed, treatment with PC-BSA was found to restore the levels of serum IL-10 which had tended to be down-regulated in CIA mice to those observed in naive mice (Fig. 3D); moreover, and consistent with a protective role for this cytokine, such IL-10 levels also inversely correlated with CIA articular disease scores (Fig. 3F). These results suggest that PC-BSA is able to reproduce the ability of ES-62 to promote IL-10 production in the CIA.
model[8]; although the cell type responsible for such IL-10 production is still unknown, it is possible that PC-BSA promotes IL-10-producing regulatory B cells, rather than regulatory T cells, as with ES-62 in CIA mice [13]. Mechanistically, since neutralizing anti-IL-10 antibodies were shown to abrogate the protective effect of IL-22 in CIA [46], such restoration of IL-10 levels by PC-BSA might impact on DC-dependent priming of Th17 and IL-17-producing γδT cells, consistent with the reduced levels of IL-17 observed in serum of PC-BSA-treated CIA mice [9]. Thus understanding the mechanisms responsible for controlling cytokine networks such as those resulting in the ES-62-mediated counter-regulation of IL-10/IL-22/IL-17 responses (Summarized in Fig. 4), rather than the analysis of the individual cytokines, may clarify the contradictory data relating to, for example, whether IL-22 is a pro- or anti-inflammatory mediator in RA.

Concluding Remarks

IL-22 was originally described as a pro-inflammatory mediator in RA. This reflects findings that mice deficient in this cytokine were resistant to developing CIA[48] as well as reports that IL-22 levels and Th22 cells are elevated in the serum of RA patients [21] and also that IL-22 has been shown to induce proliferation of human SF and promote RANKL production and osteoclastogenesis in vitro[49]. However, whilst IL-22 levels are up-regulated in RA patients and IL-22 has been shown to be involved in bone damage and RANKL production, certain studies report that such IL-22 up regulation does not contribute to the induction of synovial inflammation [21, 49-51]. Moreover, supporting our proposal of dual pathogenic and protective roles for IL-22 in RA based on the protective action of ES-62 in CIA [23], recent studies have also shown that IL-22 can play protective roles in CIA, via enhancing IL-10-mediated immunoregulation [46] and, as with ES-62, desensitizing SFs to IL-17 [52]. Collectively, these data suggest that the precise role of IL-22 in RA - protective versus pathogenic - probably depends on the inflammatory context. This is likely to especially be the case with respect to its differential effects on SFs, which in RA are subject to a complex pro-inflammatory cocktail involving cytokines, chemokines and alarmins generated by the hypoxic conditions pertaining in the arthritic joint. These results therefore question the hypothesis that serum IL-22 levels provide a pathogenic biomarker in established RA and may even suggest that IL-22 is up-regulated in a homeostatic mechanism to limit and resolve joint inflammation and promote tissue repair. In any case, they dictate that therapies targeting IL-22 should be reconsidered while the role of the cytokine in the initiation and progression of synovial inflammation in RA awaits full understanding.
